

Purpose of the staging area

From my understanding, the staging area is like a copy of the passport, and you can do whatever you want with it, such as sending the employer only the pages you need, or making marks on the copies.

We also cannot directly touch the original data, as it is often constantly changing.

We will overload the sources when querying from them directly.

Operating on the initial data may harm it unintentionally.

Why is it not possible to load data directly into the 3NF layer?

The 3NF layer requires valid data. So, we expect that no errors, missing values, duplicates occur during the process. The sources can't provide this. It will be extremely difficult to run it on-the-fly and at the same time rebuilding the structure to the normalized.
